TEKSTBILAG

VEDLEGG

Vedlegg 1, 1s

Analyseresultater av feltdubletter 1992.

Vedlegg 2, 1s

XY-diagrammer som viser analyseresultatene for feltdublettene

Vedlegg 3, 3s

Analyseresultater av reanalyse av 23 prøver fra 1985 i 1992-analyseserien.

Vedlegg 4, 1s

XY-diagrammer som viser analyseresultatene for reanalysene

Vedlegg 5, 15 s

Analyseresultater fra 1985-undersøkelsen og 1992-undersøkelsen, med 1992-resultatene omregnet til 1985-nivå

Vedlegg 6, 1 s

Prøvenummerkart

Vedlegg 7, 25 s

Kart over innhold av HNO₃-løselig fraksjon av -0.18 med mer-fraksjonen av morenens C-horisont: Al, Ca, Fe, K, Mg, Mn, Na, P, Ti, Ba, Be, Ce, Co, Cr, Cu, La, Li, Mo, Ni, Pb, Sc, Sr, V, Zn og Zr

1. INNLEDNING

En rekke geokjemiske undersøkelser har i årenes løp vært gjennomført i Nordland fylke. I 1986 ble det gjennomført en kartlegging av løsmasser, bekkesedimenter og bekkevann i hele fylket, med en prøvetakingstetthet på ca $1/30\text{km}^2$. Planene er beskrevet av Ottesen og Volden (1986), resultater for syreekstraksjon av løsmasser er rapportert av Kjeldsen (1987), mens Kjeldsen og Ottesen (1988) rapporterte innhold av gull i løsmassene. Allerede året før hadde NGU i samarbeid med Nordland fylkeskommune gjennomført en mer detaljert regional geokjemisk kartlegging i Rana og i Sulitjelma-området. Det ble da samlet løsmasseprøver og bekkesedimenter med prøvetakingstetthet $1/10\text{km}^2$. Resultatene fra løsmasseundersøkelsene i Rana er beskrevet av Krog og Næss (1986), og fra Sulitjelma-området av Næss og Krog, (1986).

For å skaffe et enhetlig geokjemisk materiale for bruk i samtaling med geofysikk og geologi i områder som ble ansett som interessante for prospektering etter sulfidmineraler og edelmetaller, ble det på oppfordring fra programledelsen utarbeidet en plan for prøvetaking og analyse av løsmasser og bekkesedimenter i de områdene som lå inntil undersøkelsesområdet i Rana fra 1985. Det ble imidlertid ikke prioritert å gå ut med ny prøvetaking for å skaffe jordprøver fra to andre tilstøtende områder som på 1970-tallet var prøvetatt svært detaljert med bekkesedimenter (Saltfjell-Svartisen).

Feltarbeid og analyser er lagt så nær opp til arbeidet i 1985 som mulig, slik at datasettene skal være sammenliknbare. I 1985 var det en forutsetning at det ble benyttet (ukvalifisert) arbeidskraft fra Arbeidsformidlingen til feltarbeidet. Feltarbeidet i 1992 ble utført av Gunnar Næss fra NGU, hvilket borger for gjennomgående høyere kvalitet enn i 1985. Rapporteringen er gjennomført noe annerledes en tilfellet var for 1985-sesongen. Metodebeskrivelse for felt og laboratorium er identisk med 1985-arbeidet. Resultatene er presentert i kart i målestokk 1:250000, men de er også tegnet sammen med resultatene fra tidligere undersøkelse, og er da bare tegnet i målestokk ca 1:1 mill.

2. METODER

2.1 FELTDATA

Det prøvetatte området er ca 700 km^2 stort og strekker seg over tre kartblad i M711-serien (målestokk 1:50000). De aktuelle kartbladene er 2027-2 Kaldvatnet, 2127-4 Virvatnet og 2128-3 Lønsdal. Det prøvetatte areal utgjør omlag 950 km^2 , og prøvetakingstettheten er dermed noe glisnere enn i 1985, nemlig ca 1 prøve/ 13 km^2 . Feltarbeidet ble gjennomført i siste halvdel av juli 1992 av Gunnar Næss alene. For å nå noen av de mest fjerntliggende lokalitetene ble det benyttet helikopter i samarbeid med NGU's geofysikere. I alt gikk det med 16 reisedøgn for feltarbeidet, reisen Trondheim - Rana innbefattet. Det ble kjørt 2560 km med bil, tilbakelagt 166 km til fots, leid båt i 3 dager og fløyet 1,18 timer med helikopter. Samlet kostnad for feltarbeidet utenom lønn og arbeidsgodtgjørelse ble i underkant av 26000 kr.

Vedlegg 6 viser prøvenummer på et kartutsnitt i 1:250000, sammen med alle lokaliteter i Rana- og Sulis-området i målestokk 1: 3 mill. På det siste kartet er lokalitetene fra 1992 skilt ut med eget symbol.

Plasseringen av prøvestedene ble planlagt før feltsesongen. Prøvetakingsområdet ble delt inn i ruter på 10 km² og innen hver rute ble det forsøkt funnet et prøvested som var mest mulig representativt for denne ruta. Prøvestedet ble dessuten lagt godt ovenfor veier, dyrka mark og andre forurensingskilder. Ved hvert prøvested ble det tatt tre prøver. To av prøvene var bekkersedimenter og den tredje prøven var en løsmasseprøve som ble tatt noen meter til side for bekken. Der det var mulig ble løsmasseprøven tatt i morenen på ca 0.5 m dyp. Mange steder var imidlertid morenematerialet svært tynt eller helt fraværende. Det ble da tatt en prøve av den løsmassen som fantes. Dette kunne medføre prøver med høyt innhold av organisk materiale.

Løsmasseprøvene ble oppbevart i papirposer som i laboratoriet på NGU ble plassert i tørkeovn og tørket ved ca 50 °C. Etter tørking ble løsmasseprøvene siktet gjennom 0.18 mm nylonduk.

2.2 ANALYSEMETODER

Sammen med prøvene fra de 70 lokalitetene samt 7 feltdubletter ble det tatt ut 23 prøver fra den analyseserien som ble gjennomført i 1985. Disse prøvene, som ble valgt fra Rana-området og representerte et utvalg av høye og lave verdier i den tidligere undersøkelsen, ble satt inn i analyseserien fra 1992 for å skaffe kontroll med analysenivåforskyvninger mellom de to datasettene. Alle de 100 prøvene ble gitt nye nummer i tilfeldig rekkefølge (randomisering) for å hindre at systematiske preparerings- eller analysefeil skulle gi geografiske mønstre som kunne mistolkes. Prøvene ble oppluttet ved at ett gram av prøvene ble veid inn i reagensglass og tilført 5 ml 7 N salpetersyre, fortynnet til 20 ml og hensatt i 3 timer ved ca 110 °C. Etter tilsats av referanseelementet yttrium og fortynning til 100 ml, ble det ved hjelp av ICP analysert 29 grunnstoffer i løsningen: Al (aluminium), Ca (kalsium), Fe (jern), K (kalium), Mg (magnesium), Mn (mangan), Na (natrium), P (fosfor), Si (silisium), Ti (titan), Ag (sølv), B (bor), Ba (barium), Be (beryllium), Cd (kadmium), Ce (cerium), Co (kobolt), Cr (krom), Cu (kobber), La (lantlan), Li (litium), Mo (molybden), Ni (nikkel), Pb (bly), Sc (skandium), Sr (strontium), V (vanadium), Zn (sink) og Zr (sirkonium). Metoden er beskrevet av Ødegård (1983).

2.3 DATABEARBEIDING

Feltkartene med prøvelokalitetene avmerket ble brukt for koordinatfesting i UTM-sone 33. (Gjeldende datum for kart var på den tiden ED50. Alle koordinater er i ettertid omregnet til WGS84 datum). Analyseresultatene ble levert i digital form og koblet med filene for randomkode og koordinater ved hjelp av geokjemisk produksjonssystem på HP 3000. Kontroll av reproduserbarhet av feltdublettene ble siden gjennomført vha DAS på PC. Nivåkontroll og -justering mellom 1985- og 1992- datasettene ble gjort med lineær regresjon vha DAS og Excel på PC, og endelig er kartene tegnet med DAS.

Dersom reproduserbarheten av 1992-prøvene ikke var god nok, eller det på grunn av stor spredning mellom gamle og nye analyser for de 23 utvalgte prøvene fra 1985-materialet ikke lot seg gjøre regne 1992-prøvene om til 1985-nivå, ble det aktuelle grunnstoffet forkastet fra det samlede datasettet. God reproduserbarhet for feltdublettene, men dårlig reproduserbarhet av reanalysene ga således grunnlag for kartframstilling av 1992-materialet, men ikke for kobling av de to datasettene til felles nivå.

Kartene er tegnet med klasseinndeling etter «Box-plot metoden», hvor data i hovedsak deles inn etter kvartiler. Avstanden i dataverdi (HS) mellom 75-prosentilen (UH) og 25-prosentilen (LH) beregnes. Øvre grenser for 6 grupper beregnes da slik:

- 1 - LH - 1.5*HS
- 2 - LH
- 3 - Median
- 4 - UH
- 5 - UH + 1.5*HS
- 6 - Maksimum

Hvis øvre grense 1 er lavere enn minimum, faller denne gruppen bort. Hvis øvre grense 5 er større enn maksimum faller også denne gruppen bort. Er det liten spredning på data blir det følgelig lite variasjon på z-skalaen på kartet. Denne metoden er velegnet for å avdekke verdier som er anomale i forhold til det datasettet det tilhører. Metoden skiller rimeligvis ikke mellom relative og absolutte anomalier; brukeren må fortsatt legge til grunn sin egen kunnskap om hva slags nivåer som er interessante i den tolkningen som skal gjøres.

3. RESULTATER

Resultatene er presentert som tabeller, diagrammer og kart; de fleste er lagt i vedleggsdelen av rapporten. Det er få interessante resultater i de 70 prøvetatte lokalitetene i arbeidet fra Rana 1992. Kommentarene til resultatene er derfor holdt på et minimum, og tatt med i dette kapittelet heller enn i et eget diskusjonskapittel.

Vurdering av feltdublettene utgjør den første kvalitetskontrollen av arbeidet. Tabell som viser disse er gjengitt i Vedlegg 1 «Analyseresultater for 7 feltdubletter løsmasser Rana 1992». Tabellen inneholder foruten analyseresultatene også stigningstallet for regresjonslinje, Pearson korrelasjonskoeffisient og tall for variasjonskoeffisienten (VK). Resultatene er illustrert i diagramform i Vedlegg 2, med unntak av grunnstoffene Si, Ag og Cd. Løselighetsparametre for Si i 7N HNO₃ er slik at løselighetsproduktet overskrides, og resultatene gir derfor ikke mening. For sølv og kadmiums vedkommende var alle verdiene på eller under deteksjonsgrensen, slik at plott av verdiene i dublettene var overflødig. Diagrammene har alle, med unntak av P, samme (logaritmiske) akseinddeling for X- og Y-aksene for hvert grunnstoff, og ved god reproduserbarhet for feltdublettene skal punktene plottet langs diagonalen. Det er da også tilfelle for alle de grunnstoffene som er plottet, bortsett fra bor, som også oppviser den høyeste gjennomsnittlige variasjonskoeffisienten av alle. Siden dublettene også utgjør et rimelig godt utvalg av høye og lave dataverdier i forhold til resten av datasettet, er B vurdert til å ikke være reproduserbart. Dette skyldes sannsynligvis at prøvene er forurenset av bor fra reagensglassene (borsilikatglass) som ble brukt under syreekstraksjonen.

Muligheten for å koble sammen analyseresultatene fra Rana 1992 med resultatene fra tilstøtende område fra 1985 er neste trinn i vurderingen av kvaliteten av resultatene. I Vedlegg 3 «Reanalyser Rana 1985/1992» er resultatene for analysene av 23 prøver innsamlet i 1985 presentert. En «R» i forkant av variabelnavnet indikerer at resultatet er oppnådd ved reanalyse i 1992; tilsvarende resultater fra 1985 er gitt lenger ut i tabellen. Under datadelen er det gitt regresjonsparametre for lineær regresjon der den gamle verdien er den avhengige variable. Regresjonsparametrene er benyttet for å regne om resultatene av de 70 1992-prøvene til 1985-nivå. Nivået fra 1985 er valgt som «sant» nivå fordi resultatene fra den gang er rapportert tidligere og utgjør den langt største delen av det samlede datasettet. Denne omregningen er ikke foretatt for dataene som er presentert i vedlegget med feltdubletter. Vedlegg 4 viser i diagramform opprinnelige og nye analyser av de 23 prøvene for de 26 grunnstoffene som også ble tegnet i feltdubletterdiagrammene.

De fleste grunnstoffene plotter rimelig bra langs regresjonslinjen i diagrammene, de samme grunnstoffene har også høye verdier for Pearson korrelasjonskoeffisient. Unntakene er B, Be og Mo. Bor ble utelukket fra 1992-datasettet pga dårlige resultater for feltdublettene. Reanalysene viser også at B-tallene fra 1992 ikke er gode. Be kan heller ikke inkluderes i det samlede datasettet. For molybden er resultatene av reanalyse katastrofalt dårlige, og Mo inkluderes derfor heller ikke i det samlede datasettet, selv om det kan tegnes kart for 1985- og 1992- datasettene hver for seg.

Den endelige tabellen over prøvenummer, koordinater og analysetall for alle 1985-prøvene og 1992-prøvene omregnet til 1985's analysenivå er gjengitt i tabell i Vedlegg 5. De variablene som det ikke har vært mulig å etablere felles nivå for, er utelatt av denne tabellen. Som Vedlegg 6 følger prøvenummerkart for de 70 lokalitetene fra 1992 i målestokk 1:250000. Som bakgrunnskart er brukt hydrografi og riksgrense fra Statens Kartverk (SK), samme målestokk. Siden lokalitetene er koordinatfestet fra kart i målestokk 1:50000, stemmer ikke alltid omrissene av innsjøer helt med lokalitetens plassering. Dette er ikke en feil ved koordinatfesting av lokalitetene, men skyldes den lavere oppløselighet i hydrografi-konturene fra SK. På samme kart er det tegnet et prøvepunkt kart for det samlede datasettet i denne rapporten, der prøvestedene fra 1992 er merket med andre symbol enn 1985-lokalitetene.

Vedlegg 7 inneholder kartene for Al, Ca, Fe, K, Mg, Mn, Na, P, Ti, Ba, Be, Ce, Co, Cr, Cu, La, Li, Mo, Ni, Pb, Sc, Sr, V, Zn og Zr. Som nevnt er alle resultatene regnet om til 1985-nivå, og det er disse tallene som er brukt ved klasseinndelingen. For Be og Mo er det avvikende prosedyre, ettersom det ikke lot seg gjøre å regne om resultatene fra 1992 til 1985-nivå. Kartene for disse to grunnstoffene inneholder derfor data slik de ble målt ved analysen i 1992, og på oversiktskartene øverst til venstre på siden er resultatene fra de 70 lokalitetene fra 1992 utelatt.

Når det gjelder data som ble rapportert i 1986, er kommentarer til disse utelatt, og leseren er overlatt til seg selv for å se 1992-resultatene i lys av 1985-resultatene ved hjelp av oversiktskartene øverst til venstre på hver side i vedlegget. Det er langt mellom de oppsiktsvekkende resultatene i materialet fra 1992.

Tabell 1 gir en summarisk oversikt over minimums-, maksimums- og gjennomsnittsverdier for datasettet fra 1992 (før omregning). Det går fram av tabellen at alle data er svært uinteressante sett fra ressursletingssynspunkt
