Introduction

This report documents all graphs of the empirical variograms and all variogram models used for kriging of the Kola project data. Journal and Huijbregts (1978)¹.

The empirical variograms have been computed in direction East-West and North-South. Distances between samples vary between 1 and 315000 meters. The finally accepted maximum number of different lags (using necessary tolerance distances) is 20. Angle tolerances are $\pm 45^\circ$. At least 40 couples of measurements have to be available for the computation of one point of an empirical variogram.

To construct the variogram models the computer program GEOSAN² was used. Model fitting was generally started by using ‘David’s Rule of Thumb’ for a spherical variogram

$$\gamma(h) = C_0 + C_1 \left(\frac{3}{2} \frac{h}{a} - \frac{1}{2} \left(\frac{h}{a} \right)^3 \right) \text{ for } h \leq a.$$

This simply means that the entire sill $C_0 + C_1$ is equal to the empirical variance. Nugget effect C_0 and range a are computed from a regression line through the first (10 %) points of the empirical variogram.

The final variogram model has been fitted by hand as an isotropical compromise using the two directional empirical variograms.

Occasionally, outliers had to be removed before starting the computation of the variograms. Where applicable, this is noted as a remark to the right of the variogram.
