Forord

I prosjekt 2439.0041 "Utluting av magnesium fra serpentin-magnesittbergarter", har Reidar Trønnes (prosjektleder) fratrådt sin stilling. Prosjektet vil fortsette med Svein Olerud og tidligere medarbeidere Per Reidar Graff og Johs Rye Røste fra kjemisiden. En finner det riktig å sammenfatte de hittil oppnådde resultater i egen rapport for derved å gi bedre grunnlag for videre arbeid. Sammenstillingen er gjort i samråd med Trønnes og Olerud.

Innledning

Det er påvist betydelige mengder talkforekomster i Raudbergfeltet, Vik i Sogn. (Bakke, 1986). Den dominerende ultramafiske bergartstype er imidlertid serpentinitt som inneholder varierende mengder magnesitt/kalsitt. Siden sammenvoksningen mellom magnesitt og serpentin er finkornet, ser det ut til å være vanskelig å skille mineralene ved fysisk oppredning. Magnesitt er lett løselig selv i fortynnet varm saltsyre. Utlutningsforsøkene som er utført ved Geokjemisk avd. (Graff og Røste 1985) viser dessuten at serpentinmineralene har stor løselighet sett i relativ til mange andre silikatmineraler som er undersøkt. Disse forsøk er utført med 6N saltsyre og 6 N salpetersyre og med koketid på 2 timer for hver prøve. Saltsyren har ca. 20 % større løseeffekt for de fleste silikatmineralgrupper, men for serpentinmineralene er løseligheten 56 - 58 % i begge syrene. Residuet på 42 - 44 % svarer til andelen av tetraederskikt (SiO_2 -tetraedre) i krystallstrukturen for serpentin. Dette indikerer at brucittskiktene er effektivt oppløst og fjernet ved utlutningsprosessen og at magnesiumioner er dominerende kationer i løsningen (Trønnes 1987). Det konkluderes videre med at prosessen kan foregå i en betydelig svakere konsentrasjon av saltsyre enn 6N eller i løpet av kortere reaksjonstid om dette skulle være ønskelig. I motsetning til serpentinmineralenes lett løselighet, løses kun 2 - 8 % av de undersøkte talkprøver. Resultatet stemmer med regelen for silikatmineralers løselighet i syre som kan uttrykkes:

Σ	Mol elementoksyder	< 1	(liten løselighet)
	Mol SiO_2	1 - 2	(diskontinuitetsområde)
		> 2	(stor løselighet)

(Graff og Røste 1985). For talk vil brucittlagene i krystallstrukturen være vanskelig tilgjengelig for syren siden de ligger mellom to tetraederskikt. Andelen av tetraederskikt i talk er dobbelt så stor som i serpentin (Trønnes 1988). Verdien av serpentin-magnesittbergarter som råstoff for magnesiumfremstilling vil ytterligere øke dersom residualmaterialet (hovedsakelig tetraederskiktene fra serpentin) også kan markedsføres. Det er foreslått å teste dette residuet til bruk som ionebytemasse (Barkey 1987) eller i forbindelse med andre anvendelsesområder.

Prøvematerialet

Til forsøkene ble det valgt ut 4 prøver av magnesittførende serpentinitt, 1 prøve magnesittfri serpentinitt og 1 prøve serpentinisert dunitt. Prøvene er tatt fra borhullene 1c, 4, 6 og 7 som ble boret under samarbeidsprosjektet mellom NGU og A/S Norwegian Talc i Raubergfeltet, Vik i Sogn, i 1984 og 1985 og er i denne rapport spesifisert i (Tabell 1) og med analyser av hovedelementer i (Tabell 2) og sporelementer i (Tabell 3).

Prosedyre for utluting

5 g pulverisert prøve (-140 mesh) ble overført til Erlenmeyer-kolber (500 ml). Kolbene var utstyrt med tilbakeløpskjølere og magnetstaver. Pulverne ble fuktet med dest. vann og kolbene tilsatte 40 ml 6N saltsyre. Kolbene ble videre utstyrt med termometre. Suspensjonene ble varmet opp til koking og holdt på koepunktet i gitte tidsintervaller (Oppvarmingstid: 10 min.). Etter avkjøling til 50 grader C ble suspensjonene filtrert gjennom glassfiber-filter (Glassfaser nr. 6) og det uløste stoff ble vasket gjentatte ganger med dest. vann. Filtreringene ble gjennomført ved hjelp av sugekolber (250 ml) og residua ble tørket ved 110 grader C. Resultatene er illustrert i (Fig 1, 2, 3, 4 og 5 og i (Tabellene 4, 5, 6 og 7).

Mikrostrukturelle forandringer ved kjemisk utluting av serpentin

Sitat fra Trønnes 1988:

Forandringen i krystallstrukturturen til serpentin ved utluting ble undersøkt ved hjelp av røntgendiffraktometer (XRD) og kjerne-magnetisk resonansspektrometer (NMR). Det ble valgt ut en serpentinittprøve fra Modum til strukturanalyse. Røntgendiffraktogram av utgangsmaterialet viser at prøven består av serpentin (antigoritt) og olivin (Fig 6). Restproduktet fra utluttingen er overveiende amorft, men to av de sterkeste refleksjonene fra antigoritt-strukturen ($7,2 \text{ \AA}$ - 001 og $3,6 \text{ \AA}$ - 002, 0012) er fremdeles synlig.

Trønnes fortsetter: Siden serpentinitprøvene har betydelig Al-innhold blir Si₂₉-toppene meget dominerende interferensfrie, og NMR-spektrene blir dermed lette å tolke. Spekteret av det ubehandlede materialet (Fig 8) har en liten topp ved $-62,5 \text{ ppm}$ (TMS) og en dominerende og skarp topp ved -95 ppm (TMS). Toppene bekrefter dominansen av silikatmineralene (Q3) i form av serpentin og tilstedevarelsen av nesosilikatmateriale (Q0) i form av olivin (Fig 4 i Kirkpatrick et al 1985 Ann. Rev. Earth Sci. 13, 29-47). Residualproduktet har en bred topp mellom -100 ppm (TMS) og -120 ppm (TMS) som svarer til tektosilikatstrukturen (Q4), sannsynligvis med flere ulike Si-posisjoner (Fig 9).

De mikrostrukturelle undersøkelsene viser at antigoritten gjennomgår en fundamental krystallstrukturell forandring gjennom utlutingsprosessen. Oktaederlagene løses opp samtidig som tetraederlagenes silikatstruktur (skiktsilikat) brytes ned og erstattes av en uordnet røntgenamorf tektosilikatstruktur.

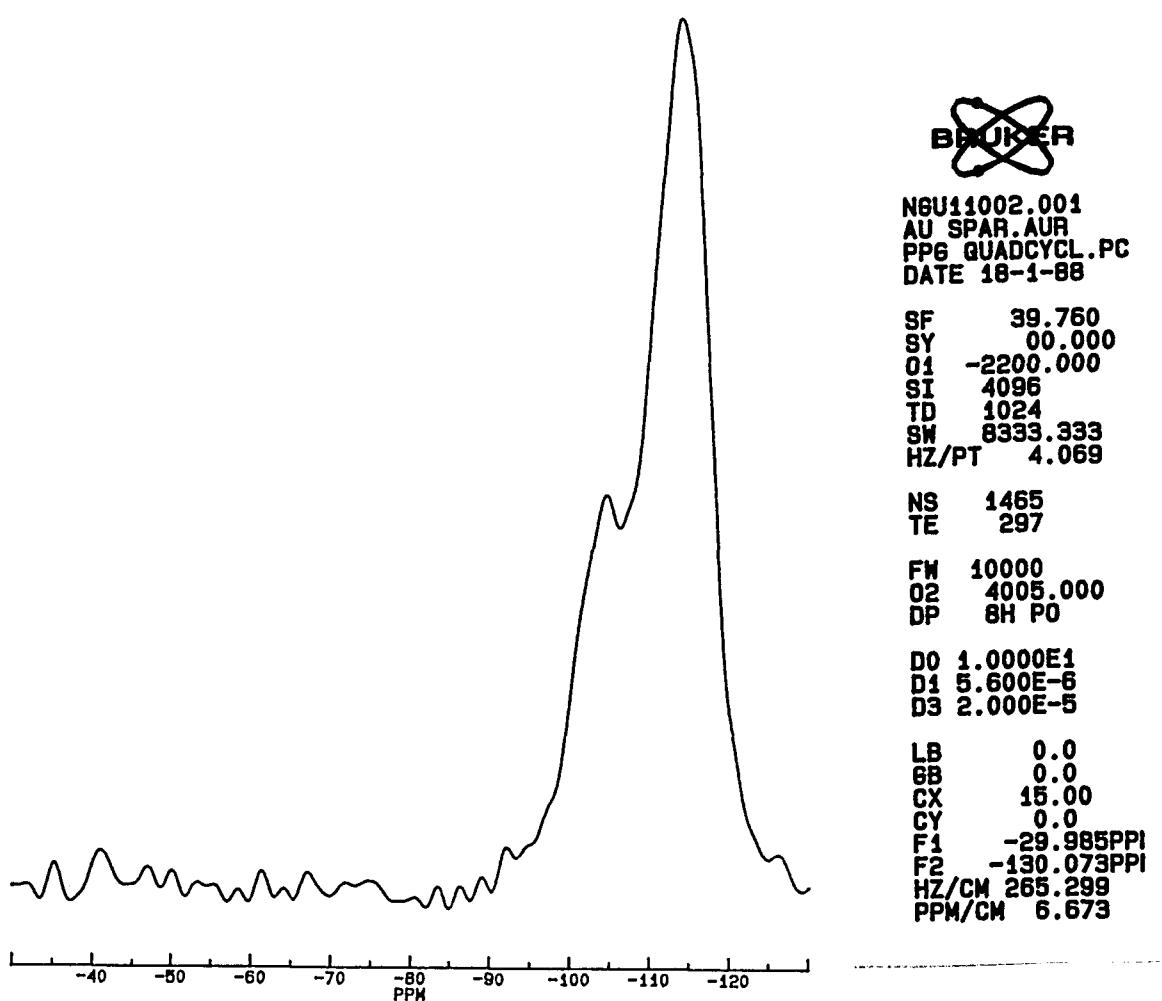

Fig 9

Forsøk mht. ionebyttereffekt av utluttet materiale

A

Ig residuum etter utlutingen ble overført til en kolonne (Fig 10). Residuet ble oppslemmet med 1N HCl og vasket med ionebyttet vann før to prøveløsninger etter tur ble kjørt gjennom massen. Prøveløsningene var nøytrale løsninger av CuSO₄, ZnSO₄ og PbSO₄. (Tabell 11) viser analyseresultatet av blindprøve og de to prøveløsningene etter passering gjennom residuet i kolonnen.

B

Residuet ble rystet i henholdsvis en 1/4 time og 1 time med Cu-Zn-Pb-løsning. Analyseresultatet av blindprøve og prøveløsninger etter rysting og filtrering er vist i (Tabell 12).

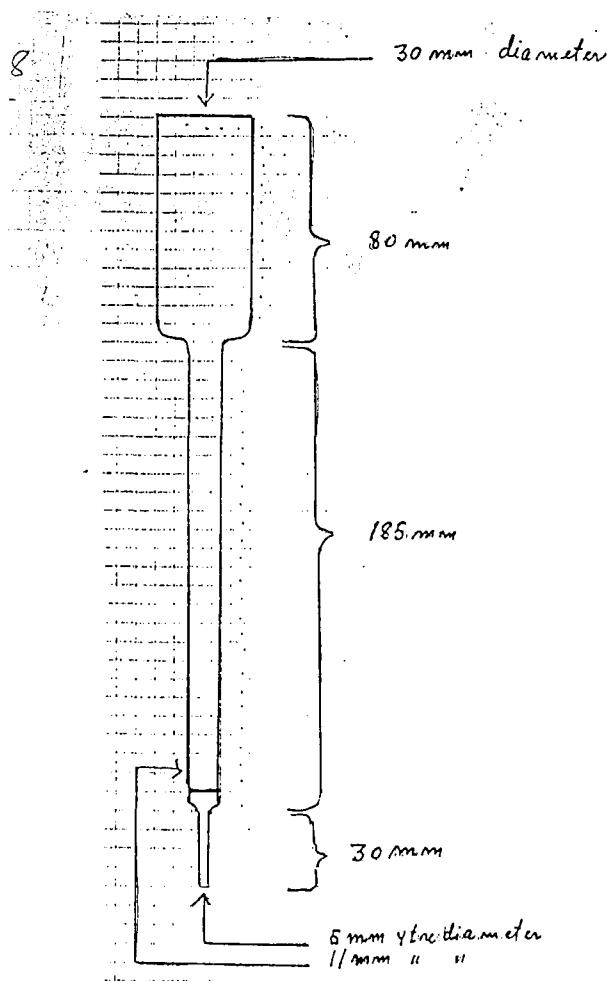

Fig 10

Konklusjon

1. Utluting av 6 serpentinitprøver i 6N saltsyre viser gjennomsnitt (X) fra 31.9 % utluting etter 1/4 time til 57.36 % utluting etter 5 timer. Etter 2 timer (den mulige aktuelle behandlings-tid) er utlutingen 49.6 % (Se tabell 4).
2. Utluting av 6 serpentinitprøver ved forskjellige syrekonsentrasjoner under ellers like forhold gir tilnærmet optimale betingelser for 6 N saltsyre (Se Tabell 5).
3. Utluting av 6 serpentinitprøver med 3N saltsyre og varierende syrevolum vise at reaksjonshastighetene er tilnærmet like (Tabell 6).
4. Utbyttet pr. minutt i gitte tidsintervaller avtar meget sterkt. I foreliggende eks. er utlutingshastigheten i tidsintervaller (1 - 2 timer) bare 4.5 % av utlutingshastigheten i tidsintervallet (0 - 1/4 timer).
5. Diffraktometeropptak av frisk og utluted serpentin (Fig 6 og 7) og NMR-opptak (Fig 8 og 9) bekrefter at det er storeforandringer i krystallstrukturen.
6. Tabeller:
 1. Prøvemateriale for utlutingsforsøk
 2. XRF-analyser av hovedkomponenter i utgangsmaterialet
 3. XRF-analyser av sporelementer i utgangsmaterialet
 4. Utluting i % ved forskjellige tider
 5. Utluting i % ved forskjellige syrekonsentrasjoner
 6. Utluting i % i 3N saltsyre men med forskjellige syremengder
 7. Utluting i gitte tidsintervaller
 8. ICP-analyse av løsning etter syrebehandling (2 timer)
 9. ICP-analyse av løsning etter syrebehandling ved forskjellige tider
 10. ICP-analyse av løsning etter behandling med forskjellige syremengder (samme konsentrasjon)
 11. ICP-analyse av løsning som har passert residuet i kolonne. Løsningen var tilslatt Cu, Ni og Pb
 12. ICP-analyse av løsning som var rystet med residuet. Rystingens varighet var 1/4 og 1 time. Løsningen var tilslatt Cu, Ni og Pb
