## **1. INTRODUCTION**

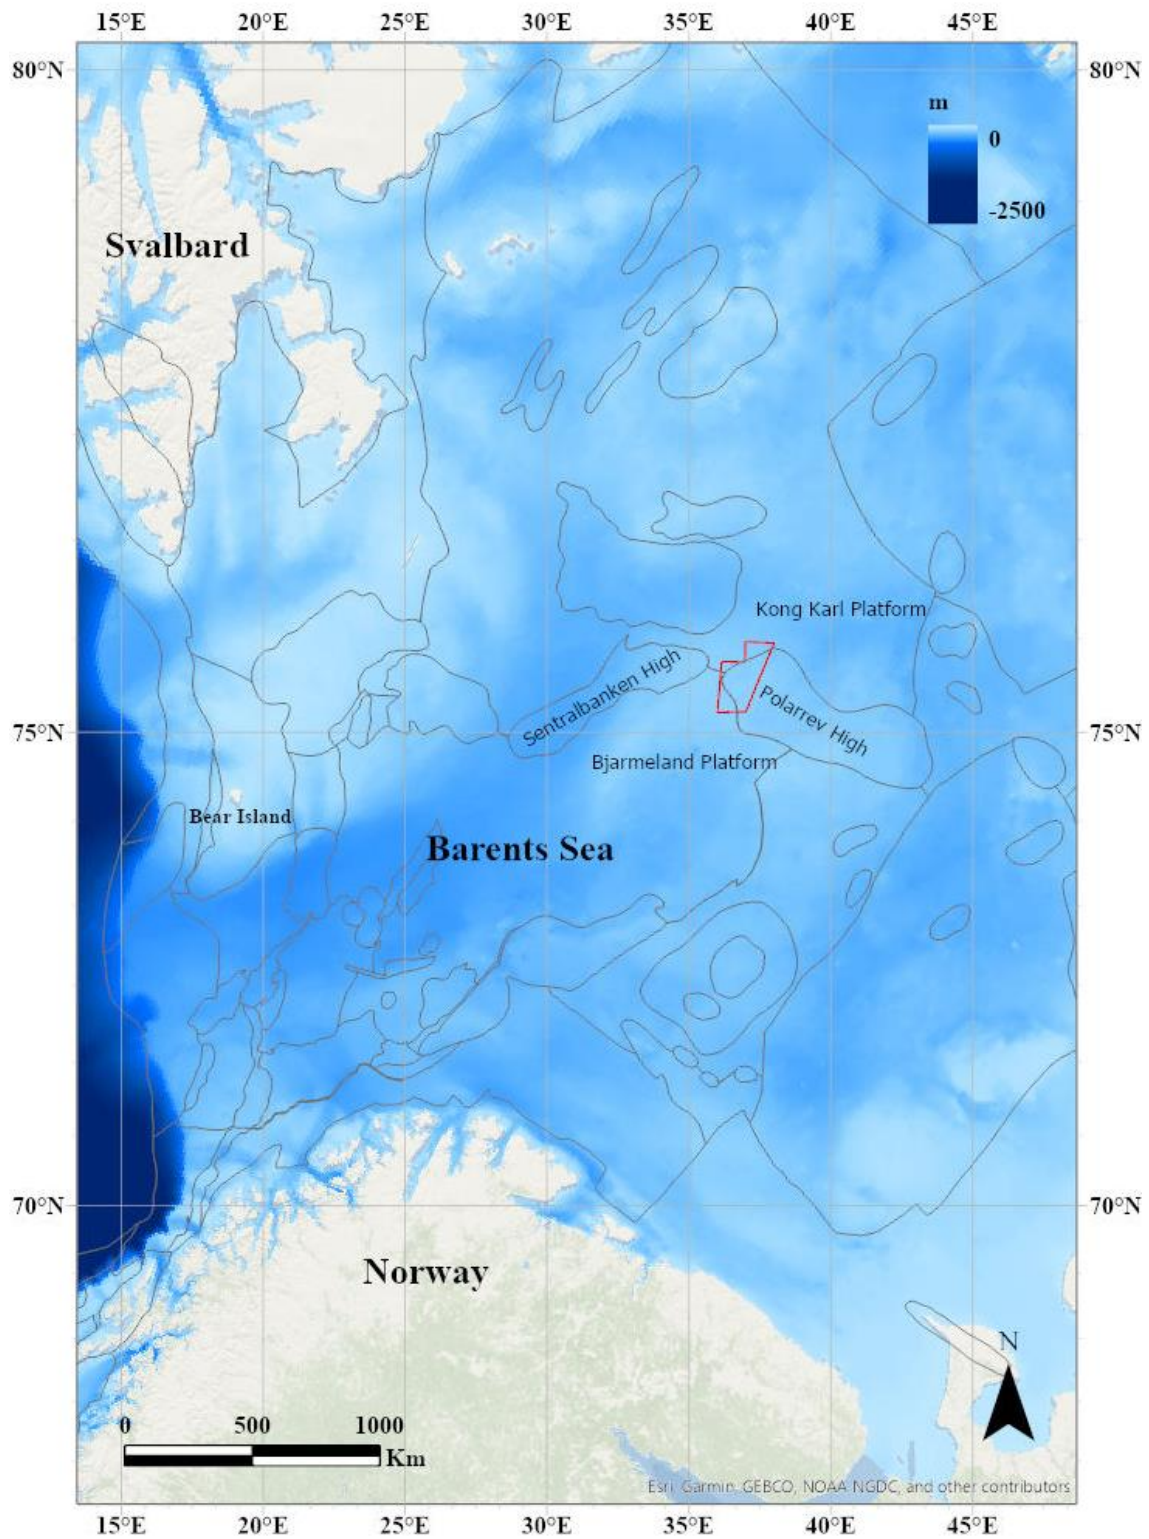

Marine methane vents and cold seeps are widespread on continental margins, including the Barents Sea (Skarke et al., 2014). Active seepage on the continental shelf is commonly associated with underlying oil and gas reservoirs, trapped gas under gas hydrates, and dissociation of gas hydrate (Milkov and Sassen, 2003). Detection of gas flares from marine methane vents and cold seeps can be efficiently detected using multibeam echosounders (Urban et al., 2017).

This study is carried out using multibeam echo sounder data collected during the Mareano surveys in 2013. The data from the surveys have been processed and interpreted in order to identify natural gas seeps, visible as gas flares, in the water column data. The data is also used for extracting bathymetry and backscatter.

## **2. STUDY AREA**

The study area lies in the Bjarmeland platform area of the southern Barents Sea (Fig. 1). The study area is mainly located over the Polarrev High with a small part lying in Kong Karl Platform and Bjarmeland platform (Fig. 1). The water depth is shallow and ranges from 150 to 225m.

*Figure 1. Regional bathymetry map of the Barents Sea showing the major structural boundaries (grey lines) and the study area (red polygon).*

### 3. METHODS

#### 3.1 Multibeam

Kongsberg EM710 multibeam system onboard ship Karoline was used by Fugro to acquire data from the study area. An important feature of the EM710 multibeam echosounder system is that it can record water column data also. The operating frequency used by EM710 (70-100 kHz) is also advantageous for the intermediate water depths, between 200 m and 1000 m, where other systems usually need a change in frequency. The operating frequency of 70-100 kHz and water depths of ca. 120 m give a Fresnel zone diameter (foot print) of around 4 m thus mapping 16 m<sup>2</sup> by each beam. As a general rule, features smaller than the size of one fourth the wavelength cannot be resolved (Sheriff, 1980). Hence, features larger than 1 meter in diameter can be theoretically detected using the system. The water column data recorded by the system can be used for detection of active gas seeps and also detection of fauna. The presence of fish schools (air in bladder) can be easily identified and is hence useful to estimate the energy loss in the water column during detailed backscatter processing. More diffuse clouds in the water column are assigned to plankton. Indications of mammals are seen as fairly large, single reflections, often associated with hyperbolic reflections.

#### 3.2 Fledermaus Software

FlederMaus (FM) Midwater package was used to process water column data for detecting and analysing gas anomalies. The data was loaded in FM Midwater along with navigation (\*.all) and converted to GWC files. During conversion, it was observed that there was fewer \*.all files present. This resulted in no navigation for some lines when converted to \*.gwc format for analysis. The \*.all file from the previous line are used to convert these \*.gwc files for possible navigation loading as a test and found that few lines have navigation located in them. The data was analysed for possible discrepancies, but some lines were converted still without any navigation, but the relative location is known from the line numbers. All the lines were hence converted with this method and interpreted. Special care was taken to go through the noisy lines to avoid any missing flares and overall, it is concluded that only weak flares might have been missed through this process.

Similar water column anomalies collected in other areas have been ground truthed confirming the feasibility of this method (Chand et al 2012a, 2012b, 2016). During interpretation, the following procedure was used:

1. The depth range was adjusted to maximise the vertical display of the line (FMM)
2. The display was adjusted to 1:1 horizontal display (FMM)
3. The colour range was adjusted to the dynamic range of signals in the water column, optimizing the display of water column features (FMM). Here we used a range between 0 and 90dB.
4. The data were inspected using the R-stack water column view, and the stacked fan water column view.

The water column data were evaluated in parallel (along-track) and perpendicular (across-track) directions to the track lines for identifying anomalies. The coordinates of potential gas

flares were recorded, along with the survey name and line ID. A subjective assessment of the apparent magnitude has been assigned (table 1). A confidence estimate is provided for codes 2-6. The maximum confidence for visual classification is 90%. A confidence of 100% is reserved for gas flares where gas bubbles have been observed by video/photo inspection or measured using gas sniffers, or where authigenic carbonate crusts have been observed. Very uncertain, but still possible gas flares have been assigned 10% confidence.

**Table 1. Codes used for assessment of magnitude, and confidence intervals.**

Code	Description	Confidence %
2	Weak gas flare	10 - 100
3	Medium strong gas flare	10 - 100
4	Strong gas flare	10 - 100
5	Very strong gas flare	10 - 100
6	Giant gas flare	10 - 100

Generally, the recognition of gas flares is based on two criteria – the bubbles have higher backscatter strength than the ambient noise in the water column data, and the objects with higher backscatter strength form characteristic patterns in the water column. Under ideal conditions, gas plumes may be observed as flare-shaped objects which start at the seabed and become narrower until they disappear at least 50-100 m above the seabed. If currents are sufficiently strong, the flares will be deflected. The identification of gas flares may be complicated due to several factors, such as high ambient (periodic or random) noise, fish schools, high density of plankton, strong and/or irregular currents, and sub-optimal intersection of the multibeam swath with the gas flare (i.e. covering only part of the flare). The MBE data can also be used to derive the seafloor reflection (i.e., backscatter) properties which will indirectly give an indication of sediment type/grain size and/or hardness of the sea bottom. The FM Geocoder package was used to process the MBE data for backscatter.

## 4. RESULTS

### 4.1 Bathymetry

The bathymetry of the study area shows a rugged seafloor eroded during last glaciation (Fig.2a). Many iceberg plough marks can be clearly seen criss-crossing the seafloor. Some pockmark-like depressions (Fig. 2b) are observed along the small basins probably indicating soft sediment deposition in these areas during and after deglaciation.

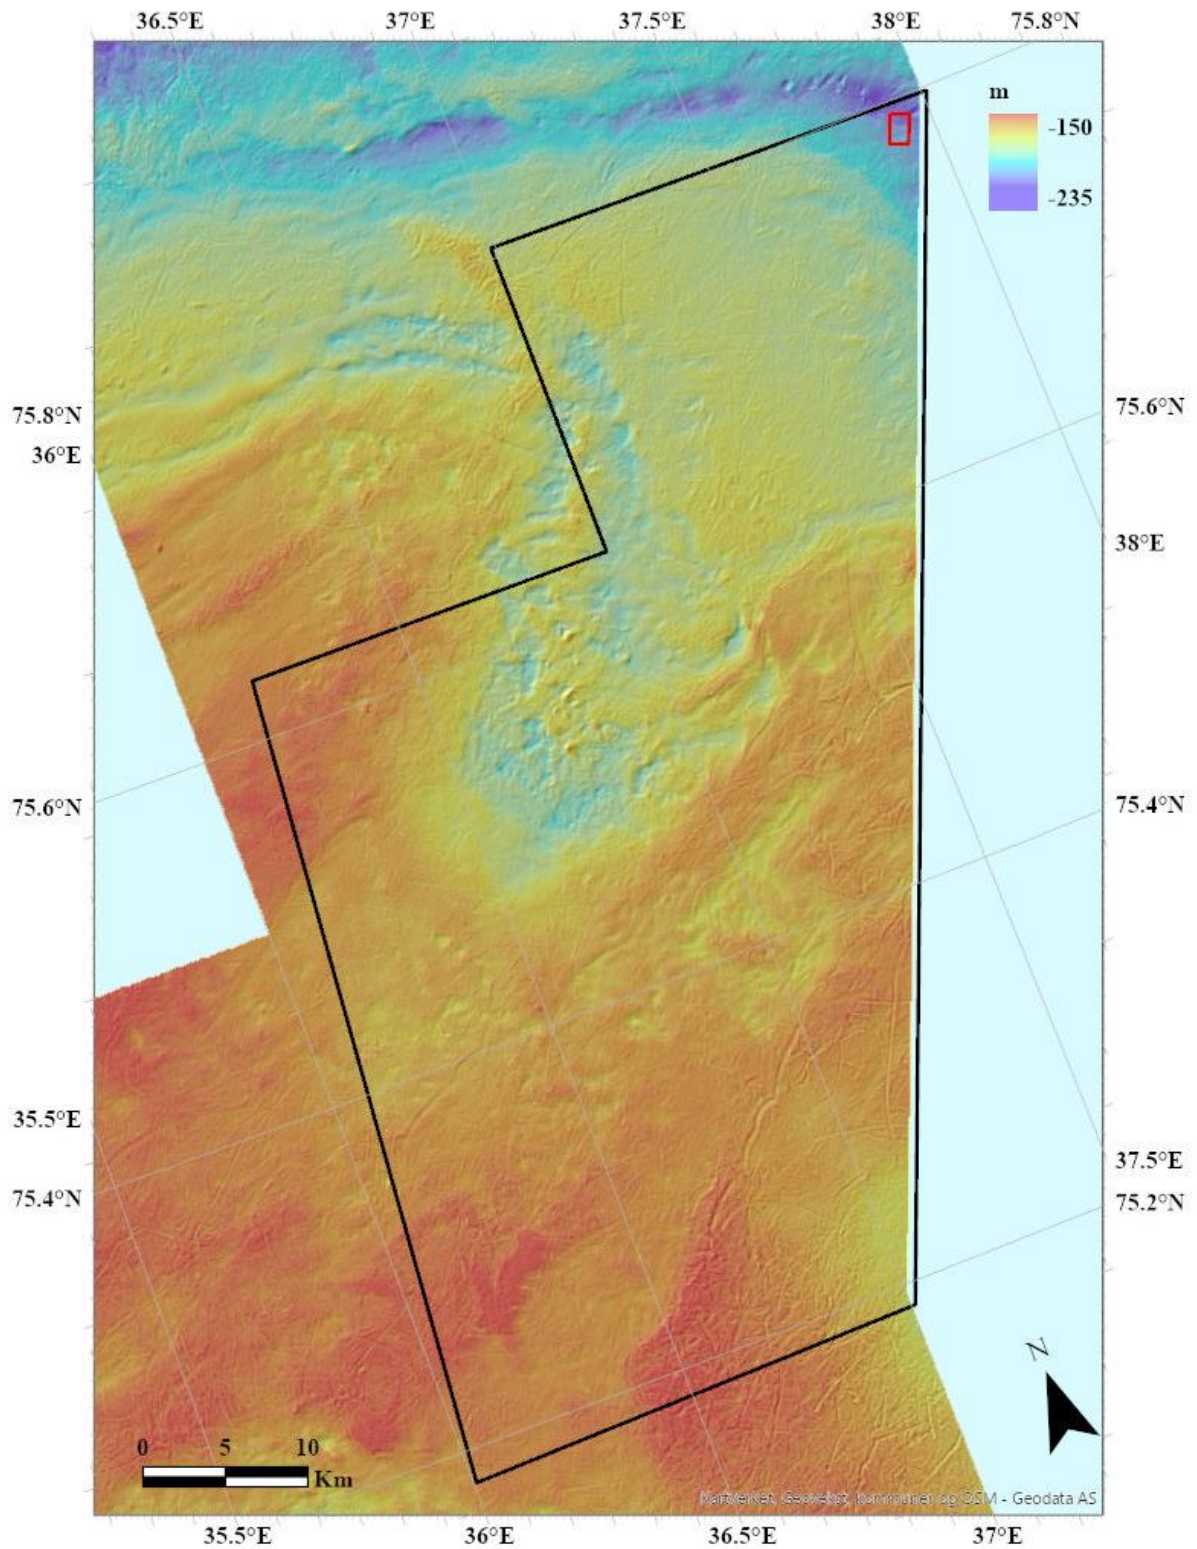

Figure 2a. Bathymetry of the study area (black polygon) and surrounding showing the detailed morphology of the seafloor. The location of Fig. 2b is also shown (red rectangle).

Figure 2b. Bathymetry from pockmark area showing their sparse distribution even in deep areas of the study area.

#### 4.2 Backscatter

The backscatter (Fig. 3) from the study area shows low values in depressions related to possible soft sediment deposition during and after deglaciation. In addition, low backscatter values are observed outside the depressions along the south-western part of the study area.

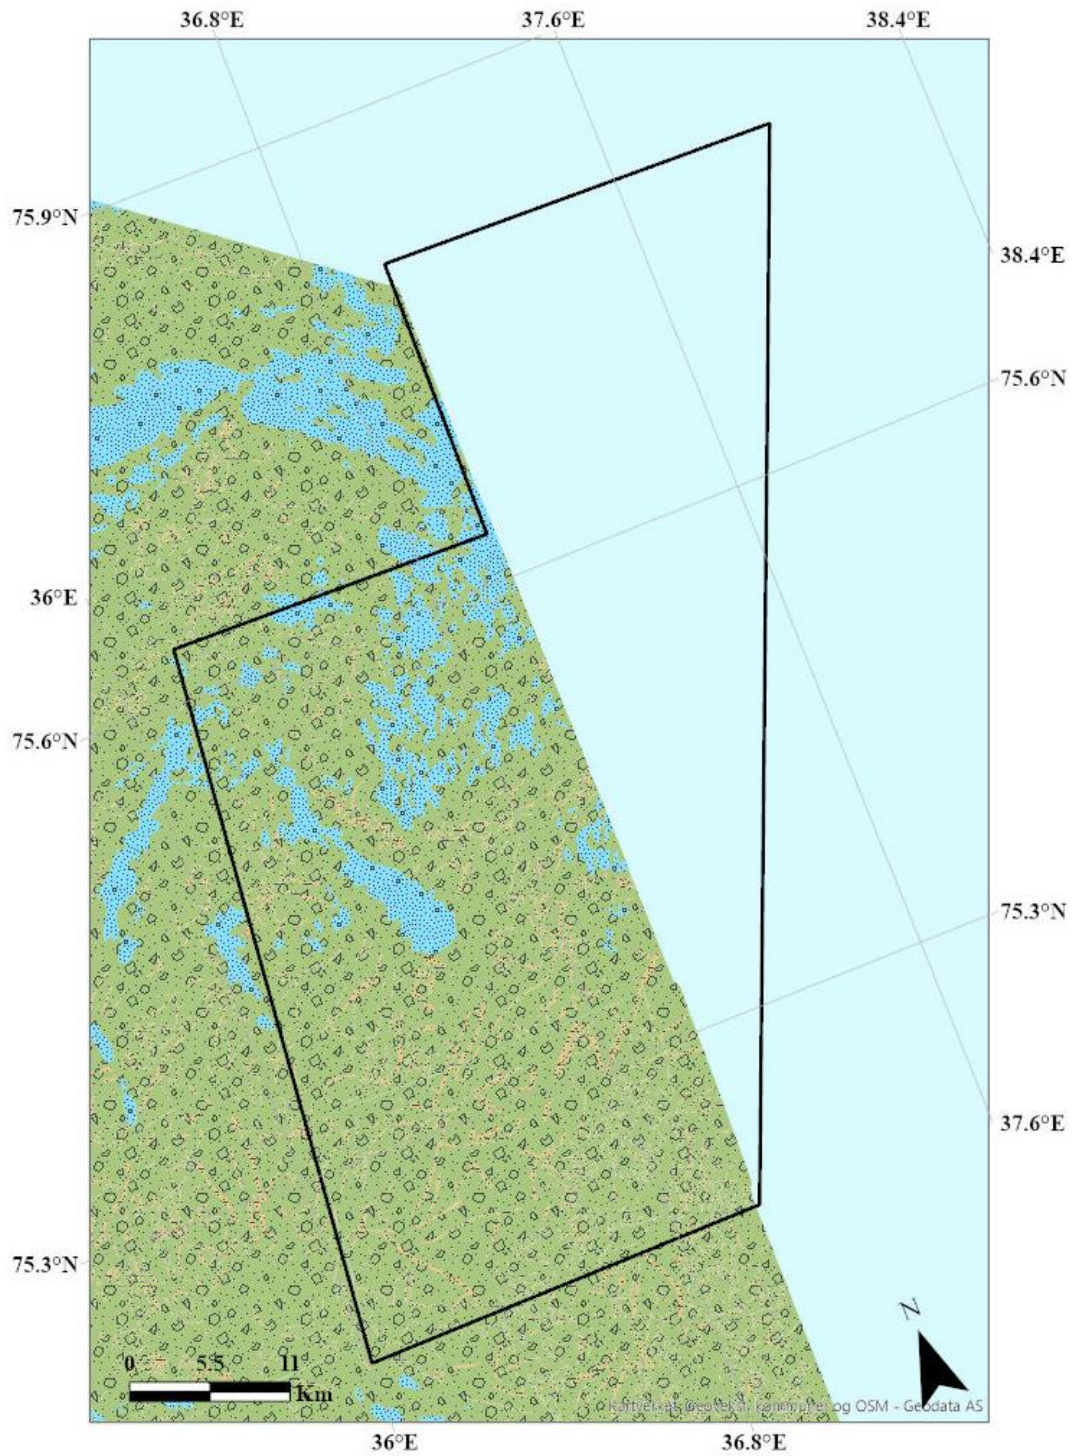

*Figure 3. Backscatter of the study area showing the locations of low backscatter concentrated mainly along depressions. Low backscatter outside depressions are indicated by red circle. The interpretation of sediment types based on various datasets along with backscatter is given in Figure 4.*

### 4.3 Sediment Classification

The sediments at the seafloor of the study area has been classified using multibeam bathymetry and backscatter together with ground truthing samples from gravity/multicore and video observations. The sediment map shows clay to sands present in the area (Fig. 4).

*Figure 4. Detailed sediment grain size map from Mareano interpretation based on various datasets covering a part of the study area.*

#### 4.4 Water Column

Several gas flares have been reported earlier from the Sentralbanken area of Barents Sea (Nixon et al., 2019). The flares are suggested to occur close to seafloor depressions formed during deglaciation (Nixon et al., 2019). The subsurface of the area indicates eroded old sedimentary rocks pinching out close to the seafloor. The present study area lies east of the Sentralbanken and mainly located along the Polarrev High (Figs. 1 & 5). The study area is covered by four Fugro surveys named as D19, D21, D23 and D26. The data includes EM710 water column measurements and the results are divided based on the survey names. The combined results from the water column data analysis of all the four survey areas are shown in Figs. 5 and 6.

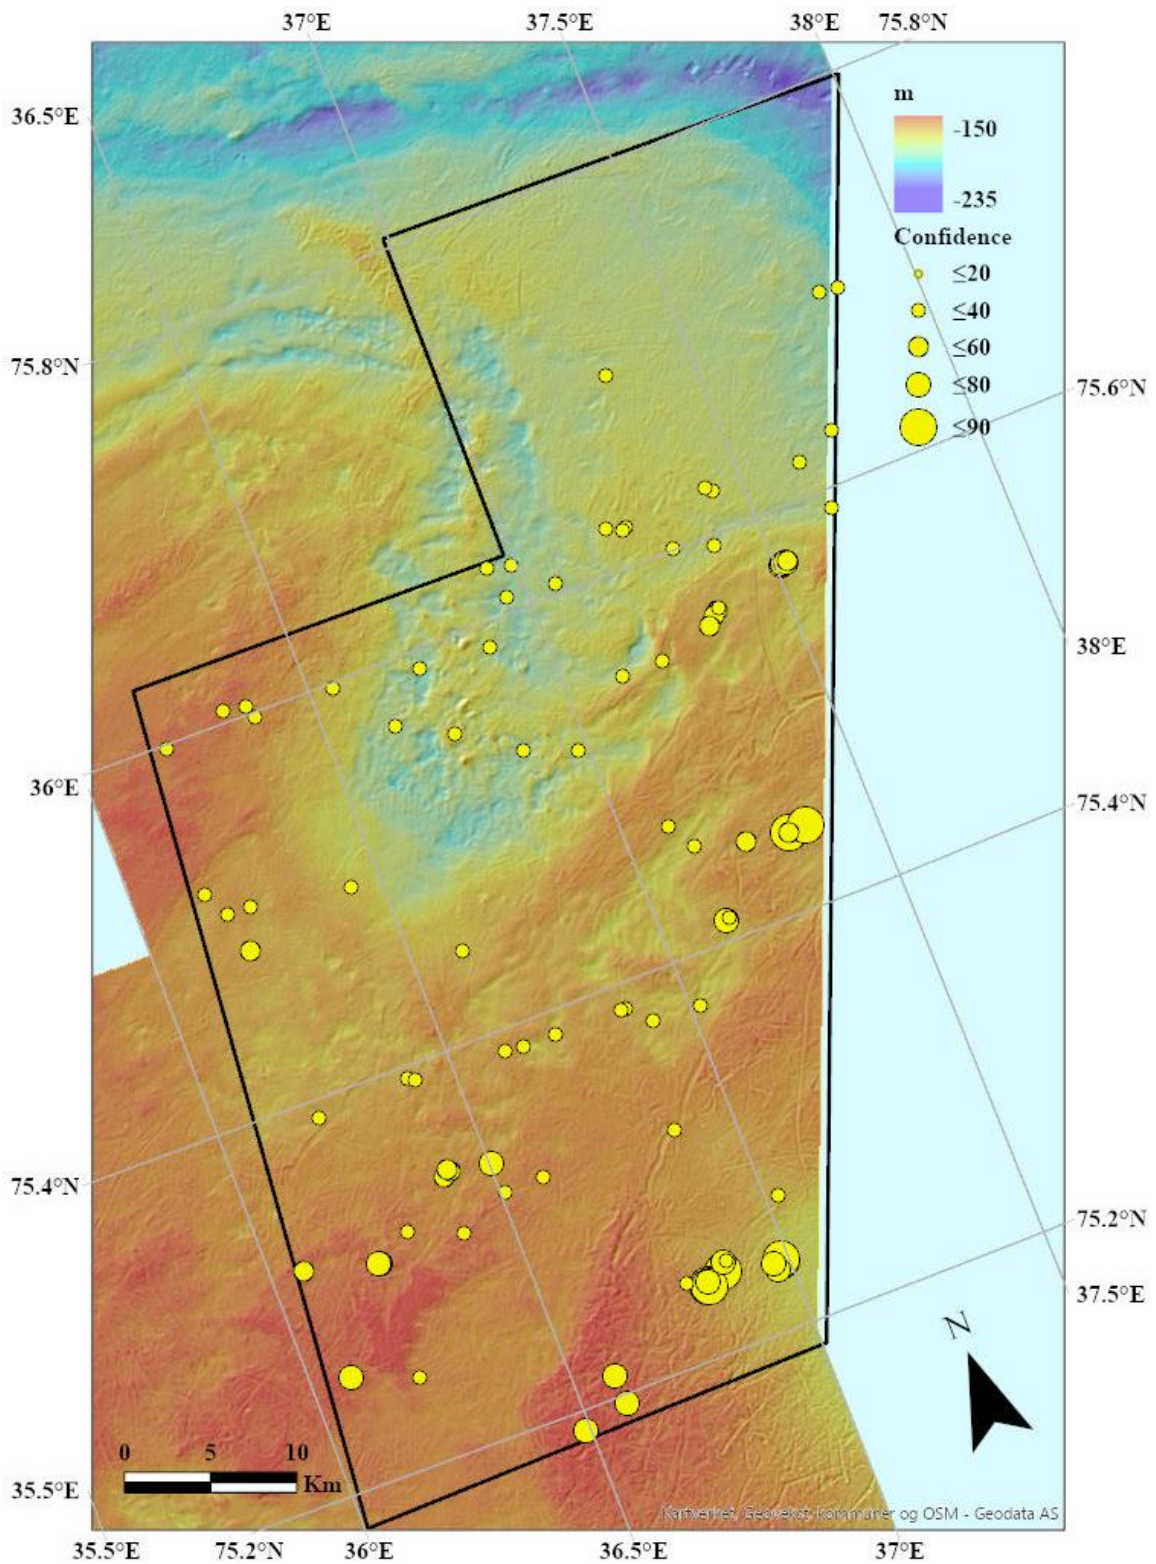

Figure 5a. Locations of flares identified from the study area and their confidence level is shown on bathymetry map of the study area.

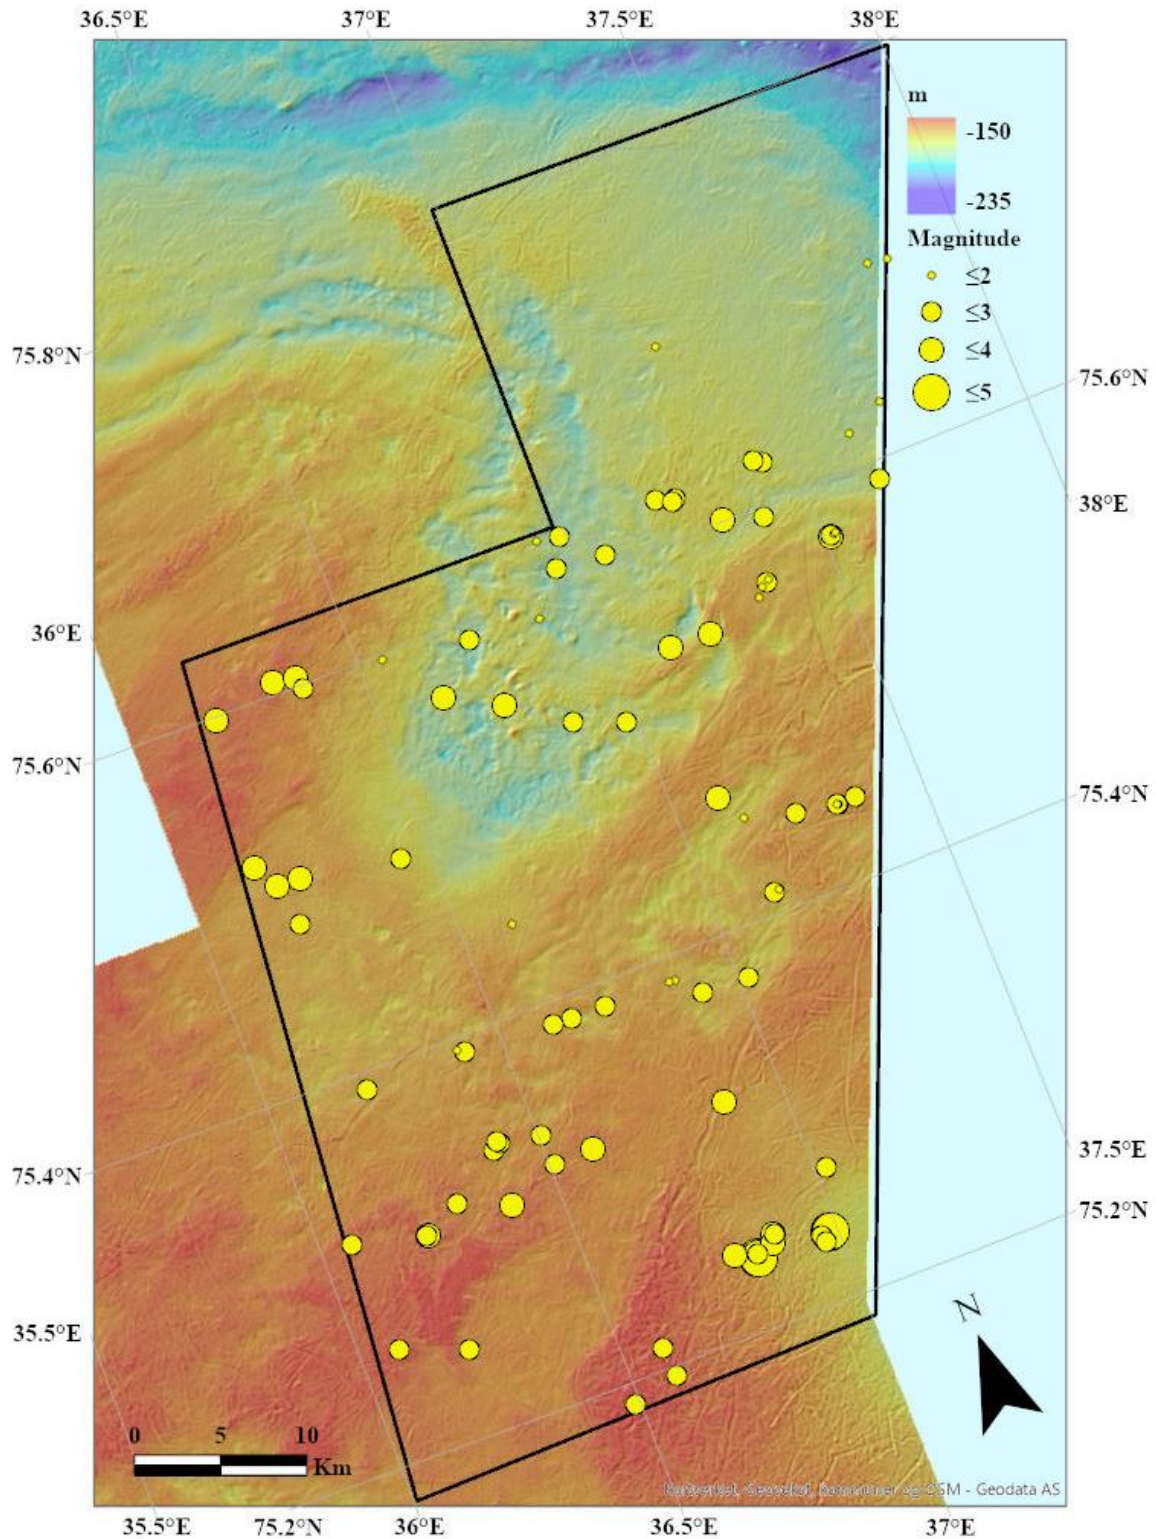

Figure 5b. Locations of flares identified from the study area and their magnitude is shown on bathymetry map of the study area.

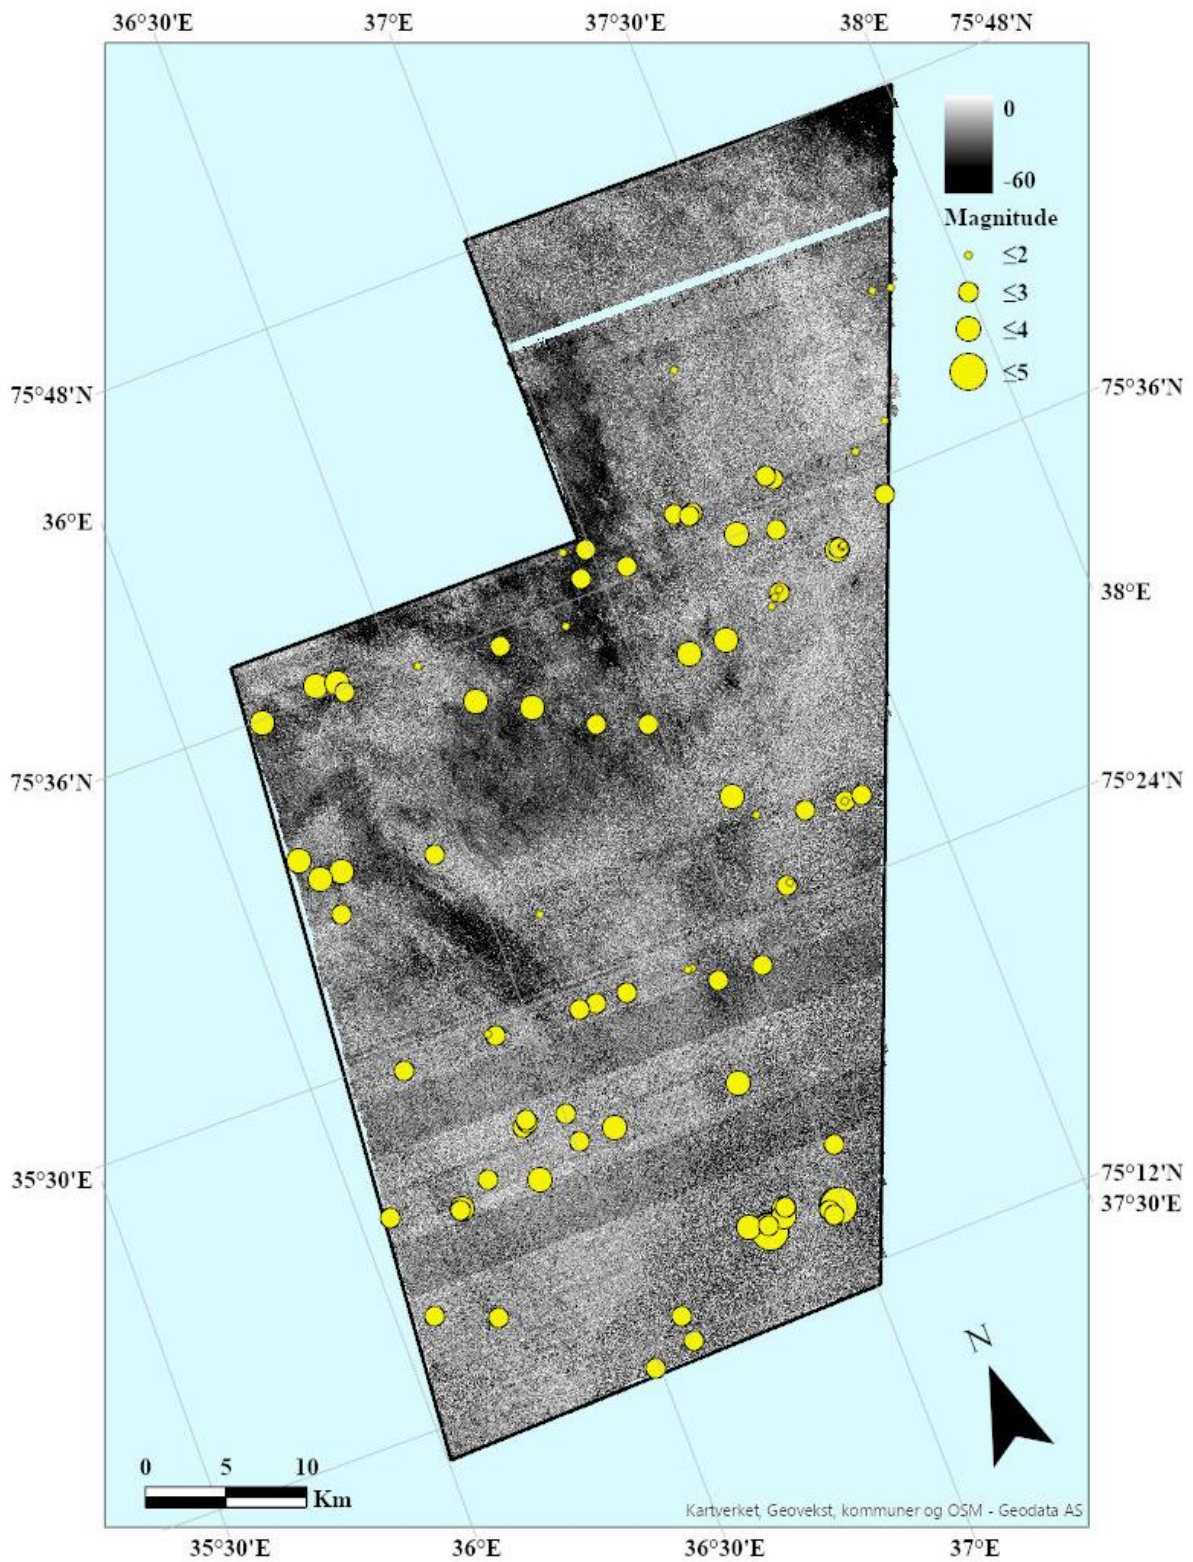

Figure 6b. Locations of flares identified from the study area and their magnitudes are shown on backscatter map of the study area.

#### 4.4.1 D19

The FOSAE-2013-D19 survey consists of 519 water column (\*.wcd) survey lines. The data was loaded in Fledermaus Midwater along with navigation (\*.all) and converted to GWC files. During conversion, it was observed that there was only 466 \*.all files present. This resulted in no navigation for the 53 lines when converted to \*.gwc format for analysis. The \*.all file from the previous line are used to convert these \*.wcd files for possible navigation loading. But only few lines were found to have navigation located in these lines. There was no flare found in the lines with missing navigation. 29 flares of varying confidence level were found in the data. The flares found are listed in Table 2. 77 lines were noisy and would have resulted in some weak flares missing. The flares identified are shown in Figures. 7 – 29.

**Table 2. Details of flares identified from Survey Area D19.**

#### 4.4.2 D21

The FOSAE-2013-D21 survey consists of 500 water column (\*.wcd) survey lines. The data was loaded in Fledermaus Midwater along with navigation (\*.all) and converted to GWC files. During conversion, it was observed that there was only 456 \*.all files present. This resulted in no navigation for the 44 lines when converted to \*.gwc format for analysis. The \*.all file from the previous line are used to convert these \*.wcd files for possible navigation loading. But only few lines were found to have navigation located in these lines. There was no flare found in the lines with missing navigation. 25 flares were found in the data of varying confidence level. The flares found are listed in Table 3. 36 lines were noisy and would have resulted in some weak flares missing. The flares identified are shown in Figures 30 – 51.

#### 4.4.3 D23

The FOSAE-2013-D23 survey consists of 754 water column (\*.wcd) survey lines. The data was loaded in Fledermaus Midwater along with navigation (\*.all) and converted to GWC files. During conversion, it was observed that there was only 706 \*.all files present. This resulted in no navigation for the 48 lines when converted to \*.gwc format for analysis. The \*.all file from the previous line are used to convert these \*.wcd files for possible navigation loading. But only few lines were found to have navigation located in these lines. There was no flare found in the lines with missing navigation. 41 flares were found in the data of varying confidence level. The flares found are listed in Table 4. 284 lines were noisy and would have resulted in some weak flares missing. The flares identified are shown in Figs. 52 – 92.

**Table 4. Details of flares identified from Survey Area D23.**

#### 4.4.4 D26

The FOSAE-2013-D26 survey consists of 457 water column (.wcd) survey lines. The data was loaded in Fledermaus Midwater along with navigation (.all) and converted to GWC files. During conversion, it was observed that there was only 402 .all files present thereby missing navigation for 55 lines. The .all file from the previous file to the .wcd file was loaded as a test and found that some lines have navigation in located in the .all file with previous line number. All the lines were converted with this method giving 426 gwc files. There were no flares found in the lines with missing navigation. 3 possible flares were found in the data of varying confidence level. The flares found are listed in Table 5. All lines had varying levels of noise (generated by other instruments or bad weather). This may have resulted in some flares missing. Special care was taken to go through these noisy lines to avoid any missing flares. Only weak flares could have been missed through this process. Many of the lines have irregular objects, with varying acoustic reflectivity (Figs. 93-94). These have been interpreted as indications of biological material, probably ranging from plankton to fish. Some indications are seen for larger objects which may be mammals. If gas flares are present on these lines, there is a significant risk that the acoustic signals from the biological material mask the presence of gas flares. Only three possible gas flares were identified from this survey. These are shown in Figs. 95-97.

**Table 5. Details of flares identified from Survey Area D26.**

Survey	LineId	Latitude	Longitude	Depth	Height	Time	Magnitude	Confidence

## 5. SUMMARY

Flares are observed with high confidence in the first three survey areas of the study area. They are distributed evenly and do not correlate with any features observed on bathymetry or backscatter data.

Details of water column acoustic gas flares found including both certain and uncertain gas flares indicate a total of 98 flares.

38 flares were identified, with a confidence level higher than 50% thus representing 40% of total flares.
